

**1. General macro concepts (20 points). Multiple choice: encircle correct answer.**

i. The following data are from an economy with 2 goods:

	2009	2010
Price good X	€ 10	€ 11
Price good Y	€ 41	€ 50
Quantity good X	90	100
Quantity good Y	100	90

How much higher is nominal GDP in 2010 than in 2009?

- a) 0%
- b) 12%**
- c) 25%
- d) None of the above are correct.

ii. Consider an economy with 2 firms. Firm A produces 200 euro worth of output using labor and 100 euro of intermediate inputs. Firm B produces 100 euro of output using only labor, and sells the output to firm A.

- a) Value added of the total economy is 200.**
- b) Value added of firm B is 0, because it uses no intermediate inputs.
- c) Value added of firm A is 200.
- d) Value added of the total economy is 300.

iii. A tourist from the US spends three nights in a hotel in Amsterdam. Which statement(s) is(are) true?

- a) This increases GDP of the Netherlands and decrease net exports of the US.
- b) This increases GDP of the Netherlands and increases consumption of the US.
- c) This increases consumption of the US, but decreases net exports of the US
- d) All of the above are correct.**

iv. Assume that money supply increases 5%, GDP increases 1%, and the velocity of money increases 2%. What is the inflation rate?

- a) 8%
- b) 6%**
- c) 4%
- d) -2%

v. What instrument can the Central Bank use to control the money supply?

- a) The reserve ratio**
- b) The inflation rate
- c) The currency-deposit ratio
- d) None of the above

vi. Can actual expenditures differ from planned expenditures, and what would happen if planned expenditures are higher than actual expenditures?

- a) No, actual and planned expenditures always are equal
- b) Yes, we then enter a recession requiring fiscal stimulus
- c) Yes, then the economy will have unplanned inventory accumulation.**
- d) None of the above

2. **A Classical economy (20 points).** An economy, without money, is described with the following accounting rules and behavioral equations:

$$Y = C + I + G + X - M, \quad Y = 1000, \quad G = 500,$$

$$C(Y-T) = 100 + \frac{2}{3}(Y-T), \quad T = 400$$

$$I(r) = 300 - 25r, \quad X = 400, \quad M = 600$$

where:  $Y$  = income/production;  $G$  = government spending;  $T$  = taxes;  $C$  = consumption;  $I$  = investment;  $X$  = exports;  $M$  = imports;  $r$  = domestic interest rate; [provide calculations, as well as numerical answers].

→ 5p for each part. 2 points subtracted for simple arithmetic errors, while approach is correct.

a. **Compute private savings, public savings and national savings, and net capital inflow.**

- $S_{private} = Y - T - C = Y - T - (100 + \frac{2}{3}(Y - T)) = 1000 - 400 - 500 = 100$
- $S_{public} = T - G = 400 - 500 = -100$
- $S_{national} = S_{private} + S_{public} = 100 + (-100) = 0$
- Capital inflow equals net exports. Hence,  $|400 - 600| = 200$

b. **What is the domestic interest rate in equilibrium?**

$$Y = 100 + \frac{2}{3}(Y - T) + 300 - 25r + G + X - M$$

$$r = \frac{1}{25} \left[ \left( 100 + \frac{2}{3}(Y - T) + 300 + G + X - M \right) - Y \right]$$

$$r = \frac{1}{25} \left[ \left( 100 + \frac{2}{3}(1000 - 400) + 300 + 500 + 400 - 600 \right) - 1000 \right] = \frac{100}{25} = 4$$

c. **If the interest rate does not change, compute what happens to income when autonomous investments falls such that investment demand is described by  $I_{new}(r) = 200 - 25r$ . (Use the Keynesian multiplier.)**

→ implicit use of multiplier is graded with full points.

$$Y = 100 + \frac{2}{3}(Y - T) + (200 - 25r) + G + X - M$$

$$\Delta Y = \frac{1}{1 - mpc} * -100 = \frac{1}{.333} * -100 = -300$$

d. **Given the change to investment in c. above, compute what happens to private and public savings.**

→ answers without computation received max 2 points

Savings with new  $Y$ :

$$S_{private} = Y - T - C = Y - T - (100 + \frac{2}{3}(Y - T)) = 700 - 400 - 300 = 0$$

$$S_{public} = T - G = 400 - 500 = -100$$

Hence, private saving decreases with 100, public savings do not change.

### Question 3 (Solow model)

- (a) Write down the equation determining the dynamics of the stock of capital per worker in the Solow model. Which flows are equal in the steady state?
- $\Delta k = sf(k) - \delta k$  (3 points)
  - In steady state investment (or savings) equal depreciation:  $sf(k) = \delta k$  (2 points)
- (b) Show in the graph, and describe what happens to steady-state capital per worker and income per worker when the rate of population growth rises in the Solow model. (1 point for labelling axes, 2 points for drawing correct functions, 2 for correctly indicating the change)

Figure 1: Answer question 3b

- Due to higher population growth( $n$ ) there is less capital per worker ( $k$ ) in equilibrium, which also lowers the income per worker ( $y$ ).
- (c) In the time series graphs, below, draw what happens to capital and output per capita ( $K/L$  and  $Y/L$ , respectively), when the savings rate is increased at time  $t$ . (5 points in total. 1 point subtracted for each 'error', which can be a jump, a wrong direction, a wrong long-term steady state)
- (d) Assume that, initially, the marginal product of capital is smaller than the depreciation rate. Draw the time path of consumption per worker ( $C/L$ ) when the savings rate is increased at time  $t$ . (5 points total. 2 points for drawing a jump, 1 for jump in the right direction, 2 for a correct long term steady state)

Figure 2: Question 2c: Capital per capita

Figure 3: Question 2c: Output per capita

Figure 4: Question 2d: Consumption per capita

#### 4. IS-LM and Mundell-Fleming Model (20 points).

- a. Draw the IS- and LM-curves (for a closed economy) in the graph below. (Do not forget to label the axes.) Show what happens to output and the interest rate in the short run following a decrease in Government spending. Describe what happens to other components of expenditures (consumption and investment).

Government spending falls;
Planned expenditure falls; income (Y) and consumption (C) fall;
IS curve shift left
Lower income reduces demand for money
Interest rate (r) falls
Lower interest rate raises investment (I)

**Total: 7 pts. [axes: 1 pt.; labelling of curves: 1 pt.; slope of curves: 1pt.; shift of curves: 2 pts.; change in C and/or I: 2 pts.]**

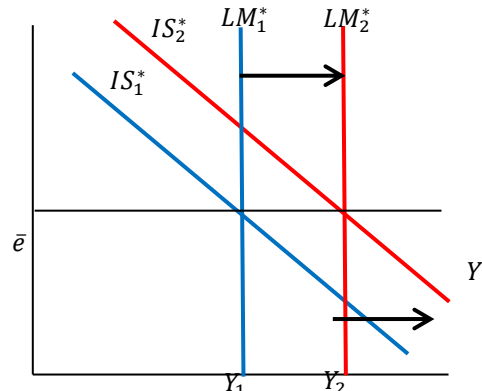

- b. For the following shocks to the EU economy (assume the EU is a closed economy), show with a '+' or '-' what happens to the interest rate ( $r$ ) and income ( $Y$ ) in the short run.

	$r$	$Y$
i. Worldwide demand for German and Italian cars increases.	+	+
ii. The Central Bank increases the money supply through purchases of govt bonds.	-	+
iii. Households foresee better times ahead and increase their consumption.	+	+
iv. A new electronic payment system using smartphones becomes generally accepted for making transactions.	-	+

**Total: 6 pts. [1.5 deduction for every wrong answer]**

- c. Consider a small open economy with a fixed exchange rate. Draw the  $IS^*$  and  $LM^*$  curves (label the axes) and show the effect of a decrease in taxes. Describe what happens to expenditures  $Y$ , its components,  $C$ ,  $I$ ,  $NX$  and to interest rate ' $r$ ' and exchange rate ' $e$ '. (use +, -, =. For example:  $Y=$ ,  $C+$ ,  $I-$ , ...)

Taxes fall; planned expenditure rises;
Income (Y) and consumption (C) rise;
Higher income raises demand for money;
To prevent increase in interest rate and
exchange rate ( $e$ ), CB raises money supply;
Investments (I) and net exports (NX) thus remain constant

**Total: 7 pts. [axes: 1 pt.; labelling of curves: 1 pt.; slope of curves: 1pt.; shift of curves: 2 pts.; change in C, NX, I and/or e, r, G: 2 pts.]**

## 5. AS-AD and Phillips-Curve (20 points).

- a. Does the short-run AS curve derived under the assumption of sticky wages slope upwards? Why?

Yes, the AS curve slopes upward, higher  $Y$  goes with higher  $P$ . If  $P$  rises more than expected, real wages fall and firms hire new workers. This implies higher production.  
(but countercyclical real wages do not seem to occur in most countries)

- b. Write down the relationship between the price level and output in the sticky price model of aggregate supply. What happens to the slope of the  $SRAS$  (short run aggregate supply) curve when the share of firms that can always adjust prices increases?

$P = P^e + b(Y - \bar{Y})$ , with  $b = \frac{a(1-s)}{s}$ , with  $s$  is fraction sticky firms.  
when more firms can adjust response of output to unexpected price change is smaller. So, AS is steeper.  
 $s$  goes down, curve is steeper.  
intuition. There are less firms that can't adjust prices and react with output.

- c. Write down the Phillips curve and describe the trade-off that the Phillips curve implies. What happens to the Phillips curve, and the position of the economy on a Phillips curve in the short and long run after the Central Bank increases the growth rate of the money supply? (state which assumption you make about price expectations)

$\pi = \pi^e - B(U - \bar{U}) + \epsilon$   
Assume rational: after announcement,  $\pi^e$  increases.  $U$  stays at  $\bar{U}$  and  $\pi$  rises.  
Assume adaptive: after announcement, income increases,  $U$  decreases. Expected inflation is equal to inflation before announcement. So, actual  $\pi$  will increase.  
But, as  $\pi$  increases,  $\pi^e$  goes up next year, curve shifts, and slowly  $U$  goes back to  $\bar{U}$ . Economy ends up with  $U = \bar{U}$  and higher  $\pi$ . But, it had period of lower unemployment, during transition.
